

DRP 2026 Abstract

Sam Shady

September 2026

Combinatorial game theory is the study of 2-player turn-based games that do not involve randomness or hidden information. Common examples are chess and tic-tac-toe. Impartial games are combinatorial games in which both players have the same moves available from any given position. Remarkably, all positions in all impartial games have an equivalent position in the impartial game Nim. In this presentation we will explore how Nimbers play a crucial role in making that equivalence.
